**Author** C.W.**Issues** <http://github.com/pyexcel/Flask-Excel/issues>**License** New BSD License**Development** 0.0.5**Released** 0.0.5**Generated** August 21, 2016

Here is a typical conversation between the developer and the user:

```
User: "I have uploaded an excel file"
      "but your application says un-supported file format"
Developer: "Did you upload an xlsx file or a csv file?"
User: "Well, I am not sure. I saved the data using "
      "Microsoft Excel. Surely, it must be in an excel format."
Developer: "OK. Here is the thing. I were not told to support"
      "all available excel formats in day 1. Live with it"
      "or delay the project x number of days."
```

**Flask-Excel** is based on [pyexcel](#) and makes it easy to consume/produce information stored in excel files over HTTP protocol as well as on file system. This library can turn the excel data into a list of lists, a list of records(dictionaries), dictionaries of lists. And vice versa. Hence it lets you focus on data in Flask based web development, instead of file formats.

The idea originated from the common usability problem when developing an excel file driven web applications for non-technical office workers: such as office assistant, human resource administrator. The fact is that not all people know the difference among various excel formats: csv, xls, xlsx. Instead of training those people about file formats, this library helps web developers to handle most of the excel file formats by providing a common programming interface. To add a specific excel file format to your application, all you need is to install an extra pyexcel plugin. No code change to your application.

The highlighted features are:

1. excel data import into and export from databases
2. turn uploaded excel file directly into Python data structure
3. pass Python data structures as an excel file download
4. provide data persistence as an excel file in server side
5. supports csv, tsv, csvz, tsyz by default and other formats are supported via the following plugins:

Table 1: A list of file formats supported by external plugins

Plugins	Supported file formats
<a href="#">pyexcel-xls</a>	xls, xlsx(r), xlsm(r)
<a href="#">pyexcel-xlsx</a>	xlsx
<a href="#">pyexcel-ods3</a>	ods (python 2.6, 2.7, 3.3, 3.4)
<a href="#">pyexcel-ods</a>	ods (python 2.6, 2.7)
<a href="#">pyexcel-text</a>	(write only)json, rst, mediawiki, html latex, grid, pipe, orgtbl, plain simple

This library makes information processing involving various excel files as easy as processing array, dictionary when processing file upload/download, data import into and export from SQL databases, information analysis and persistence. It uses [pyexcel](#) and its plugins:

1. to provide one uniform programming interface to handle csv, tsv, xls, xlsx, xlsm and ods formats.

2. to provide one-stop utility to import the data in uploaded file into a database and to export tables in a database as excel files for file download.
3. to provide the same interface for information persistence at server side: saving a uploaded excel file to and loading a saved excel file from file system.

---

## Installation

---

Recently, pyexcel(0.2.2+) and its plugins(0.2.0+) started using newer version of setuptools. Please upgrade your setup tools before install latest pyexcel components:

```
$ pip install --upgrade setuptools
```

You can install it via pip:

```
$ pip install Flask-Excel
```

or clone it and install it:

```
$ git clone http://github.com/pyexcel/Flask-Excel.git
$ cd Flask-Excel
$ python setup.py install
```

Installation of individual plugins , please refer to individual plugin page. For example, if you need xls file support, please install pyexcel-xls:

```
$ pip install pyexcel-xls
```

### Setup

---

In your application, you must import it before using it:

```
from flask.ext import excel
```

or:

```
import flask.ext.excel
```

---

## Quick start

---

A minimal application may look like this:

```
from flask import Flask, request, jsonify
from flask.ext import excel

app=Flask(__name__)

@app.route("/upload", methods=['GET', 'POST'])
def upload_file():
    if request.method == 'POST':
        return jsonify({"result": request.get_array(field_name='file')})
    return '''
    <!doctype html>
    <title>Upload an excel file</title>
    <h1>Excel file upload (csv, tsv, csvz, tsvz only)</h1>
    <form action="" method=post enctype=multipart/form-data><p>
    <input type=file name=file><input type=submit value=Upload>
    </form>
    '''

@app.route("/download", methods=['GET'])
def download_file():
    return excel.make_response_from_array([[1,2], [3, 4]], "csv")

@app.route("/export", methods=['GET'])
def export_records():
    return excel.make_response_from_array([[1,2], [3, 4]], "csv", file_name="export_data")

# insert database related code here

if __name__ == "__main__":
    app.run()
```

The tiny application exposes two urls: one for file upload and the other for file download. The former url presents a simple file upload html and responds back in json with the content of the uploaded file. Here is an *example file* <[https://github.com/pyexcel/Flask-Excel/blob/master/examples/example\\_for\\_upload.csv](https://github.com/pyexcel/Flask-Excel/blob/master/examples/example_for_upload.csv)> for testing but you can upload any other excel file. The file upload handler uses `request.get_array` to parse the uploaded file and gets an array back. The parameter `file` is coded in the html form:

```
<input ... name=file>
```

**Warning:** If ‘field\_name’ was not specified, for example `request.get_array('file')` in `upload_file()` function, your browser would display “Bad Request: The browser (or proxy) sent a request that this server could not understand.”

The latter simply throws back a csv file whenever a http request is made to <http://localhost:5000/download/>. `excel.make_response_from_array` takes a list of lists and a file type as parameters and sets up the mime type of the http response. If you would like to give ‘tsvz’ a go, please change “csv” to “tsvz”.

---

## More excel file formats

---

The example application understands csv, tsv and its zipped variants: csvz and tsvz. If you would like to expand the list of supported excel file formats (see [A list of file formats supported by external plugins](#)) for your own application, you could install one or all of the following:

```
pip install pyexcel-xls  
pip install pyexcel-xlsx  
pip install pyexcel-ods
```

**Warning:** If you are using pyexcel <=0.2.1, you still need to import each plugin manually, e.g. *import pyexcel.ext.xls* and Your IDE or pyflakes may highlight it as un-used but it is used. The registration of the extra file format support happens when the import action is performed

---

## Data import and export

---

Continue with the previous example, the data import and export will be explained. You can copy the following code in their own appearing sequence and paste them after the place holder:

```
# insert database related code here
```

Alternatively, you can find the complete example on [github](#)

Now let's add the following imports first:

```
from flask.ext.sqlalchemy import SQLAlchemy # sql operations
import pyexcel.ext.xls # import it to be able to handle xls file format
```

Now configure the database connection. Sqlite will be used and **tmp.db** will be used and can be found in your current working directory:

```
app.config['SQLALCHEMY_DATABASE_URI'] = 'sqlite:///tmp.db'
db = SQLAlchemy(app)
```

And paste some models from Flask-SQLAlchemy's documentation:

```
class Post(db.Model):
    id = db.Column(db.Integer, primary_key=True)
    title = db.Column(db.String(80))
    body = db.Column(db.Text)
    pub_date = db.Column(db.DateTime)

    category_id = db.Column(db.Integer, db.ForeignKey('category.id'))
    category = db.relationship('Category',
        backref=db.backref('posts', lazy='dynamic'))

    def __init__(self, title, body, category, pub_date=None):
        self.title = title
        self.body = body
        if pub_date is None:
            pub_date = datetime.utcnow()
        self.pub_date = pub_date
        self.category = category

    def __repr__(self):
        return '<Post %r>' % self.title

class Category(db.Model):
    id = db.Column(db.Integer, primary_key=True)
    name = db.Column(db.String(50))
```

```
def __init__(self, name):
    self.name = name

def __repr__(self):
    return '<Category %r>' % self.name
```

Now let us create the tables in the database:

```
db.create_all()
```

Write up the view functions for data import:

```
@app.route("/import", methods=['GET', 'POST'])
def doimport():
    if request.method == 'POST':
        def category_init_func(row):
            c = Category(row['name'])
            c.id = row['id']
            return c
        def post_init_func(row):
            c = Category.query.filter_by(name=row['category']).first()
            p = Post(row['title'], row['body'], c, row['pub_date'])
            return p
        request.save_book_to_database(field_name='file', session=db.session,
                                      tables=[Category, Post],
                                      initializers=(category_init_func,
                                                    post_init_func))

        return "Saved"
    return '''
<!doctype html>
<title>Upload an excel file</title>
<h1>Excel file upload (xls, xlsx, ods please)</h1>
<form action="" method=post enctype=multipart/form-data><p>
<input type=file name=file><input type=submit value=Upload>
</form>
'''
```

In the code, *category\_init\_func* and *post\_init\_func* are custom initialization functions for Category and Post respectively. In the situation where you want to skip certain rows, None should be returned and flask\_excel will ignore the row.

Write up the view function for data export:

```
@app.route("/export", methods=['GET'])
def doexport():
    return excel.make_response_from_tables(db.session, [Category, Post], "xls")
```

Then run the example again. Visit <http://localhost:5000/import> and upload `sample-data.xls`. Then visit <http://localhost:5000/export> to download the data back.

---

## Export filtered query sets

---

Previous example shows you how to dump one or more tables over http protocol. Hereby, let's look at how to turn a query sets into an excel sheet. You can pass a query sets and an array of selected column names to `make_response_from_query_sets()` and generate an excel sheet from it:

```
@app.route("/custom_export", methods=['GET'])
def docustomexport():
    query_sets = Category.query.filter_by(id=1).all()
    column_names = ['id', 'name']
    return excel.make_response_from_query_sets(query_sets, column_names, "xls")
```

Then visit [http://localhost:5000/custom\\_export](http://localhost:5000/custom_export) to download the data .. \_data-types-and-its-conversion-funcs:

---

## All supported data types

---

The example application likes to have array but it is not just about arrays. Here is table of functions for all supported data types:

data structure	from file to data structures	from data structures to response
dict	<code>get_dict()</code>	<code>make_response_from_dict()</code>
records	<code>get_records()</code>	<code>make_response_from_records()</code>
a list of lists	<code>get_array()</code>	<code>make_response_from_array()</code>
dict of a list of lists	<code>get_book_dict()</code>	<code>make_response_from_book_dict()</code>
<code>pyexcel.Sheet</code>	<code>get_sheet()</code>	<code>make_response()</code>
<code>pyexcel.Book</code>	<code>get_book()</code>	<code>make_response()</code>
database table	<code>save_to_database()</code>	<code>make_response_from_a_table()</code>
a list of database tables	<code>save_book_to_database()</code>	<code>make_response_from_tables()</code>
a database query sets		<code>make_response_from_query_sets()</code>

See more examples of the data structures in [pyexcel documentation](#)

---

## API Reference

---

**Flask-Excel** attaches **pyexcel** functions to **Request** class.

### 8.1 ExcelRequest

`flask_excel.ExcelRequest.get_sheet (field_name=None, sheet_name=None, **keywords)`

#### Parameters

- **field\_name** – the file field name in the html form for file upload
- **sheet\_name** – For an excel book, there could be multiple sheets. If it is left unspecified, the sheet at index 0 is loaded. For ‘csv’, ‘tsv’ file, **sheet\_name** should be None anyway.
- **keywords** – additional keywords to `pyexcel.get_sheet ()`

#### Returns

A sheet object

The following html form, the `field_name` should be “file”:

```
<!doctype html>
<title>Upload an excel file</title>
<h1>Excel file upload (csv, tsv, csvz, tsvz only)</h1>
<form action="" method=post enctype=multipart/form-data><p>
<input type=file name=file><input type=submit value=Upload>
</form>
```

`flask_excel.ExcelRequest.get_array (field_name=None, sheet_name=None, **keywords)`

#### Parameters

- **field\_name** – same as `get_sheet ()`
- **sheet\_name** – same as `get_sheet ()`
- **keywords** – additional keywords to pyexcel library

#### Returns

a two dimensional array, a list of lists

`flask_excel.ExcelRequest.get_dict (field_name=None, sheet_name=None, name_columns_by_row=0, **keywords)`

#### Parameters

- **field\_name** – same as `get_sheet ()`
- **sheet\_name** – same as `get_sheet ()`

- **name\_columns\_by\_row** – uses the first row of the sheet to be column headers by default.
- **keywords** – additional keywords to pyexcel library

**Returns** a dictionary of the file content

```
flask_excel.ExcelRequest.get_records(field_name=None, sheet_name=None, name_columns_by_row=0, **keywords)
```

### Parameters

- **field\_name** – same as `get_sheet()`
- **sheet\_name** – same as `get_sheet()`
- **name\_columns\_by\_row** – uses the first row of the sheet to be record field names by default.
- **keywords** – additional keywords to pyexcel library

**Returns** a list of dictionary of the file content

```
flask_excel.ExcelRequest.get_book(field_name=None, **keywords)
```

### Parameters

- **field\_name** – same as `get_sheet()`
- **keywords** – additional keywords to pyexcel library

**Returns** a two dimensional array, a list of lists

```
flask_excel.ExcelRequest.get_book_dict(field_name=None, **keywords)
```

### Parameters

- **field\_name** – same as `get_sheet()`
- **keywords** – additional keywords to pyexcel library

**Returns** a two dimensional array, a list of lists

```
flask_excel.ExcelRequest.save_to_database(field_name=None, session=None, table=None, initializer=None, mapdict=None, **keywords)
```

### Parameters

- **field\_name** – same as `get_sheet()`
- **session** – a SQLAlchemy session
- **table** – a database table
- **initializer** – a custom table initialization function if you have one
- **mapdict** – the explicit table column names if your excel data do not have the exact column names
- **keywords** – additional keywords to `pyexcel.Sheet.save_to_database()`

```
flask_excel.ExcelRequest.save_book_to_database(field_name=None, session=None, tables=None, initializers=None, mapdicts=None, **keywords)
```

### Parameters

- **field\_name** – same as `get_sheet()`
- **session** – a SQLAlchemy session

- **tables** – a list of database tables
- **initializers** – a list of model initialization functions.
- **mapdicts** – a list of explicit table column names if your excel data sheets do not have the exact column names
- **keywords** – additional keywords to `pyexcel.Book.save_to_database()`

## 8.2 Response methods

`flask_excel.make_response (pyexcel_instance, file_type, status=200, file_name=None)`

### Parameters

- **pyexcel\_instance** – `pyexcel.Sheet` or `pyexcel.Book`
- **file\_type** – one of the following strings:
  - ‘csv’
  - ‘tsv’
  - ‘csvz’
  - ‘tsvz’
  - ‘xls’
  - ‘xlsx’
  - ‘xlsm’
  - ‘ods’
- **status** – unless a different status is to be returned.
- **file\_name** – provide a custom file name for the response, excluding the file extension

`flask_excel.make_response_from_array (array, file_type, status=200, file_name=None)`

### Parameters

- **array** – a list of lists
- **file\_type** – same as `make_response ()`
- **status** – same as `make_response ()`
- **file\_name** – same as `make_response ()`

`flask_excel.make_response_from_dict (dict, file_type, status=200, file_name=None)`

### Parameters

- **dict** – a dictionary of lists
- **file\_type** – same as `make_response ()`
- **status** – same as `make_response ()`
- **file\_name** – same as `make_response ()`

`flask_excel.make_response_from_records (records, file_type, status=200, file_name=None)`

### Parameters

- **records** – a list of dictionaries

- **file\_type** – same as `make_response()`
- **status** – same as `make_response()`
- **file\_name** – same as `make_response()`

```
flask_excel.make_response_from_book_dict(book_dict,           file_type,           status=200,  
                                         file_name=None)
```

### Parameters

- **book\_dict** – a dictionary of two dimensional arrays
- **file\_type** – same as `make_response()`
- **status** – same as `make_response()`
- **file\_name** – same as `make_response()`

```
flask_excel.make_response_from_a_table(session,           table,           file_type           status=200,  
                                         file_name=None)
```

Produce a single sheet Excel book of `file_type`

### Parameters

- **session** – SQLAlchemy session
- **table** – a SQLAlchemy table
- **file\_type** – same as `make_response()`
- **status** – same as `make_response()`
- **file\_name** – same as `make_response()`

```
flask_excel.make_response_from_query_sets(query_sets,   column_names,   file_type   sta-  
                                             tus=200,file_name=None)
```

Produce a single sheet Excel book of `file_type` from your custom database queries

### Parameters

- **query\_sets** – a query set
- **column\_names** – a nominated column names. It could not be None, otherwise no data is returned.
- **file\_type** – same as `make_response()`
- **status** – same as `make_response()`
- **file\_name** – same as `make_response()`

```
flask_excel.make_response_from_tables(session,       tables,       file_type       status=200,  
                                         file_name=None)
```

Produce a multiple sheet Excel book of `file_type`. It becomes the same as `make_response_from_a_table()` if you pass `tables` with an array that has a single table

### Parameters

- **session** – SQLAlchemy session
- **tables** – SQLAlchemy tables
- **file\_type** – same as `make_response()`
- **status** – same as `make_response()`
- **file\_name** – same as `make_response()`

## Change log

---

### 9.1 0.0.5 - 21.08.2016

1. compatibility with pyexcel v0.2.2: automatic discovery of pyexcel plugins.
2. #15: file name may have more than one dot

### 9.2 0.0.4 - 15.01.2016

1. #8: set file name in response

### 9.3 0.0.3 - 01.07.2015

1. code refactoring. less code lines in Flask-Excel and more reusable code in pyexcel-webio

### 9.4 0.0.2 - 21.05.2015

1. turn query sets into a response

### 9.5 0.0.1 - 22.01.2015

Mix pyexcel into Flask.request and bring more make\_response functions.
